ABSTRACT

Background: Hospitals are the largest and most costly operating units of health systems, and their share of current government expenditures in the healthcare sector is between 50 and 80 percent. The hospital efficiency is more indicative of the proper function of the resources devoted to it. The aim of this study was to evaluate the efficiency of hospitals in Tabriz by using the Pabon Lasso model.

Methods: This is a descriptive study that investigated the efficiency of Tabriz hospitals during 2009-2013. All hospitals of Tabriz were entered by census. Data (bed occupancy rate, bed turnover and patient length of stay) were collected in summer 2014 and charts were plotted using SPSS₁₉ software.

Results: The mean of Pabon Lasso's three indices of efficiency in 5 years (excluding psychiatric beds) was 67.6% for bed occupancy rate, 104.3 times bed turnover, and 2.48 days average patient length of stay. The coefficient of bed occupancy increased by 3% over 5 years, the bed turnover index increased by 8 times and the average length of stay decreased by 0.17 day. On average, 25.2% of hospitals were in Region 1, 23.5% in Region 2, 26.1% in Region 3 and 25.2% in Region 4 of Pabon Lasso Diagram.

Conclusion: The presence of 26% of hospitals in the region of Pabon Lasso Diagram shows the effective efficiency of hospitals which is not an acceptable statistics for hospitals and requires the intervention of health practitioners and policymakers.

Keywords: Pabon Lasso, Efficiency, Hospital

Introduction

Over the last decade, the health sector in most countries has faced a significant increase in health care costs and in particular, rise in hospital costs (1). Hospitals, as one of the most important community health centers, are also the largest and most costly operational units of these centers. It accounts for 50 to 80% of government expenditure in the health sector, and in other statistics, based on WHO report, in third world countries, half of the national cost is spent on these centers (2-5).

Moreover, by spending these huge resources in these institutions, their efficiency must be carefully measured. One of the ways to accurately measure efficiency is to adapt to standards (6). Hospital efficiency standards can be evaluated in different aspects, such as quality, efficiency, productivity and accessibility (7). One of the models that is currently used considering the necessity of observing the principle of productivity in the optimal use of resources is efficiency evaluation using hospital efficiency indices (8). Efficiency in brief means maximizing the use of resources to generate returns. In order to determine the efficiency or inefficiency of each firm, appropriate indicator or indices should be used as a criterion (9). The most important and most effective indices of efficiency measurement are bed occupancy rate, bed turnover, and the average length of stay (10, 11). The criteria defined for the above indices by the Ministry of Health and Medical Education of Iran fall into three levels: desirable, moderate and undesirable (12). Based on the I.R.Iran budget organization of 2002, approximately 300 billion Rials are wasted annually for unused hospital beds, which according to the calculations of the Central Bank of the Islamic Republic of Iran, has 9 times the value in the year 2016 (base on inflation). This is why many patients cannot be admitted due to lack of access to a hospital bed or for other reasons (6, 13).

One of the useful ways to evaluate the efficiency of the three above-mentioned indices is to use the Pabon Lasso model. This model was introduced in 1986 by Pabon Lasso and was used to evaluate the efficiency of hospitals (14). The benefits of using

the Pabon Lasso model include the rapid identification of poorly functioning health centers, the identification of regions requiring improvement, and the identification of useful strategies to improve the efficiency of health centers (15). In this model, hospitals are located in four regions; each region represents the type of efficiency and resource efficiency according to the type of hospital expertise.

Based on the Pabon Lasso model, the status of the health centers in each of the four regions and the interpretation of each region is as follows:

Region 1 (Southwest side of the chart): Low bed occupancy rate and low bed turnover rate, this feature is specific to centers where bed supply is more than demand for health care. Region 2 (northwestern side of the chart): Low bed occupancy rate and high bed turnover rate indicate the unnecessary hospitalization of patients and the extra bed capacity in health centers (characteristics of Obstetrics and Gynecology departments).

Region 3 (Northeastern side of the chart): High bed occupancy rate and high bed rate, these centers have a good efficiency despite the use of the minimum number of beds. Region 4 (Southeast side of the chart): High bed occupancy rate and low bed turnover rates indicate long-term hospitalization, low utilization of outpatient facilities and high costs (characteristics of psychiatric and elderly care centers).

Due to lack of a similar study in Tabriz and the importance of these indices in improving the behavior of managers in the allocation and utilization of resources as well as country studies, generally carried out using one-year data (14, 16-20), this study was conducted to investigate the efficiency of hospitals in Tabriz during the 5-year period from 2009-2013.

Materials and Methods

This is a descriptive and retrospective study conducted in 2014. Sampling was done in a census that included all 21 hospitals in Tabriz (11 university hospitals and 10 non-university hospitals). The study data covers the five year

period from 2009 to 2013. The Pabon Lasso model was used to evaluate the efficiency of health centers in this study. In this model, the horizontal axis chart shows the percentage of bed occupancy and the vertical axis represents the bed turnover rate and the parallel axis with these two (vertical and horizontal axes) represents the length of stay. Therefore, a point on parallel axes by a line drawn from the origin of the coordinates and the point obtained from the two available indices indicate the average length of stay, and this value is increased uniformly from left to right and up to down (21).

The aim of this study was to measure the efficacy of hospitals affiliated with Tabriz University of Medical Sciences using the Pabon Lasso chart. Indices required to evaluate the efficiency of health centers were obtained by a questionnaire based on the indices of the Ministry

of Health and through the treatment Deputy of Tabriz University of Medical Sciences (12). SPSS₁₉ software was used for data analysis and illustrate the Pabon Lasso chart.

In addition, the declaration of Helsinki was considered for ethical issues.

Results

Among the 21 hospitals studied, the efficiency indices including the average percentage of bed occupancy, the average bed turnover, and the average length of stay within 5 years (including psychiatric hospitals and without it) are presented in Table 1.

According to the results, during the 5 years of investigation, the distribution of hospitals studied in the 4 regions of Pabon Lasso is described in Table 2 and Figure 1.

Figure 1. Overview of the hospitals in Tabriz during 2009-2013

The status of hospitals in Tabriz from 2009 to 2013 indicated the presence of an average 25.2% of hospitals in Region 1, 23.5% in Region 2, 26.1% in Region 3, and 25.2% in Region 4.

Changes in the regions during the 5-year period increased for regions one (25 to 33.3%) and three (25 to 28.5%), and decreased for regions two (20 to 14.2%) and four (30 to 23.8%).

The status of the hospitals according to specialty is as follows:

The highest and lowest occupancy rates were found in single psychiatric hospitals (88.09, one hospital) and ophthalmology hospitals (47.60, two hospitals). Also, the highest and lowest bed turnover were assigned to single-specialized hospitals with Obstetrics and Gynecology specialties (128.40, 5 hospitals) and psychiatry (11.53, one hospital), respectively. The highest and lowest average stay are related to single-specialized hospitals with psychiatric specialties

(27.76, one hospital) and ophthalmology (1.65, two hospitals).

The growth of the number of existing hospitals during 2009-2013 in Regions 1, 2, 3, and 4 equals -5, +5, -5, +5%, respectively (excluding the hospital with incomplete information). These results reveal the negative growth of Regions 2 and 4, as well as the positive growth of Regions 1 and 3. The

percentage of hospital distribution in the four regions of Pabon Lasso was equal. In the 5-year period (2009-2013), Pabon Lasso's one and three diagrams were evaluated as undesirable and desirable in terms of efficiency. On average, we witnessed the presence of 25% (five) hospitals in these two regions (Table 2).

Table 1. Comparison of the three indices of hospital efficiency with desirable situation from the perspective of the Ministry of Health

Year	Bed occupancy (%)	The percentage of desirable bed occupancy from the perspective of the Ministry of Health	Average bed turnover (rank / year)		The average desirable bed turnover from the perspective of the Ministry of Health	Average stay (day)		The average desirable stay from the perspective of the Ministry of Health
			including the hospital or psychiatry specialty	excluding psychiatric hospital		including the hospital or psychiatry specialty	excluding psychiatric hospital	
2009	65.1	Above 70%	93.6	98	More than 24 times	3.87	2.59	Less than 3.5 days
2010	65.8	Above 70%	98.1	102.7	More than 24 times	3.80	2.52	Less than 3.5 days
2011	67.2	Above 70%	102.7	107.1	More than 24 times	3.42	2.44	Less than 3.5 days
2012	68.9	Above 70%	102.8	107.3	More than 24 times	3.76	2.47	Less than 3.5 days
2013	68.2	Above 70%	101.5	106.1	More than 24 times	3.75	2.42	Less than 3.5 days
Mean	67.6	Above 70%	99.8	104.3	More than 24 times	3.72	2.48	Less than 3.5 days

Table 2. Distribution of studied hospitals in Pabon Lasso Quadruples from 2009 to 2013

Year	Region 1		Region 2		Region 3		Region 4	
	Number	Percentage(%)	Number	Percentage(%)	Number	Percentage(%)	Number	Percentage(%)
2009	5	25%	4	20%	5	25%	6	30%
2010	5	25%	5	25%	5	25%	5	25%
*2011	4	19%	7	33.3%	5	23.8%	5	23.8%
*2012	5	23.8%	5	23.8%	6	28.5%	5	23.8%
*2013	7	33.3%	3	14.2%	6	28.5%	5	23.8%
Mean (%)		25.2%		23.5%		26.1%		25.2%

* Information of one of the hospitals (with psychiatric specialty) due to lack of data has been registered only from 2011 to 2013.

Discussion

The aim of this study was to evaluate the efficiency of hospitals in Tabriz during 5 years. Based on the results, an average of 67.6% bed occupancy, and 104.3 times of annual bed turnover, and 2.48 days of average length of stay (excluding hospitals of psychiatric specialty) and comparison of these indices with the standards of the Ministry of Health and Medical Education, hospitals in Tabriz are in a desirable level in terms of bed turnover index and average length of stay and also a moderate rate of bed occupancy. Also, based on the comparison of efficiency indices from 2009 to 2013, it was found that the index of bed occupancy rate increased by 3% during 5 years, the bed turnover index increased by 8 times and the average length of stay decreased by 0.17 day. These figures indicate the growth of efficiency indices studied over the past 5 years. Therefore, hospitals should take measures such as patient reception and create new specializations for admitting patients to improve their bed occupancy rate.

The comparison of indices with the study of Miraki et al. (21), 2007- 2011 and Rezaei et al. (22) 2006-2011 revealed that the average of the indices studied in Tabriz hospitals was higher than the hospitals of Kurdistan University of Medical Sciences (bed occupancy rate = 62.5, average stay = 3.4, bed turnover = 79) and Kermanshah University of Medical Sciences (bed occupancy rate 64.4, average stay = 3.7, bed turnover = 81.8). However, the results of Miraki et al. (21), revealed that the health centers from 2007, which included 25% of the health centers (3 regions) in the first region, 25% of the health centers (3 centers) in the second region, 33% of the health centers (4 centers) in the third region, and 17% of health centers (2 centers) were in the fourth region which reached 8% (1 center), 41% (5 centers), 33% (4 centers) and 17% (2 centers) in 2011, which had a more satisfactory progress than the present study (22). Although the efficiency status of Pabon Lasso in Tabriz hospitals is in poor condition compared to other provinces such as Isfahan, Shiraz and Kerman,

hospitals in Tabriz showed better efficiency than the above hospitals when comparing the bed indices (20, 22). One of the reasons for this difference is the fact that the bed turnover in the Tabriz hospitals is higher because the horizontal axis of the Pabon Lasso chart is higher than the rest of the country and, accordingly, more hospitals fall in Regions 1 and 4.

In this study, during five years, the number of hospitals in Region 1 of the Pabon Lasso model increased. These hospitals should increase the bed turnover and occupancy rate of the hospital bed with measures such as preventing the expansion of the center and, if possible, transferring a number of existing beds to the treatment center and using them in other medical centers covered by the university (15).

Due to the nature of ophthalmology and obstetrics hospitals (low bed occupancy rate and high bed turnover), Region 2 represents the undesirable condition of some hospitals with non-ophthalmology and maternity specialties. During the 5 year period of this study, the number of hospitals in the region decreased. The remaining hospitals in the region can take steps to improve their living standards, reduce the number of beds and reduce the number of unnecessary hospital beds. The status of the hospitals in Region 3 is desirable and there should be planning for the performance stability and the improvement of the hospitals using the lowest number of beds (21). The nature of mental and elderly hospitals is such that they have low bed turnover and high bed occupancy rates due to the treatment of chronic diseases. An important strategy to improve the efficiency of these centers is to emphasize cost reduction, quality improvement and outpatient services (15, 23). Hospitals located in low-efficiency regions are mainly affected by the presence of excess beds or poor distribution of beds between the departments, low quality of provision of services and low affordability in low income groups, the absence of a covered region and in the proximity of hospitals, failure to comply with the requirements for service leveling by providers all are controversial (22).

Conclusion

The further growth of Region 1 compared to Region 3 in 5 years indicates the negative growth in the efficiency and improvement of Tabriz hospitals. Although the three indices have increased during this period, which is necessary for the survival of hospitals in the present age, lack of improvement in the efficiency and allocation of resources in the present time, will affect the improvement and advancement of the quality of health services in the future including financial, qualitative, human and technology challenges. It is suggested that unnecessary hospitalization be reduced by facilitating home care. In addition, paying more attention to the health sector, and increasing the capacity of hospital beds should be on the agenda. Actions such as recognizing the capabilities and facilities in the health and medical networks, adequate funding and required human resources,

applying the principles of scientific management in health centers, leveling the provision of services at different levels of the health care network system will also be helpful.
